

### Exercise 1

Let  $Y$  be a count variable which is modeled by a Poisson regression model

$$Y|x \sim \text{Poisson}(\lambda(x))$$

where  $\mathbb{E}(Y|x) = \lambda(x) = \exp(\beta_0 + x\beta_1)$  and where  $x$  is the covariate of interest.

We assume a random sample with independent observation pairs  $(y_i, x_i)$  for  $i = 1, \dots, n$ . Define  $\beta = (\beta_0, \beta_1)^\top$  and  $Z_i = (1, x_i)^\top$  so that  $Z_i^\top \beta = \beta_0 + x_i\beta_1$ .

- (a) Write down the log-likelihood for  $\beta$ .
- (b) Write down the score equation (= first derivative of the log-likelihood).
- (c) Write down the Fisher information matrix.

### Exercise 2

Consider the simple linear regression model

$$Y = X\beta + \varepsilon,$$

where  $Y = (Y_1, \dots, Y_n)^\top$ ,  $\varepsilon = (\varepsilon_1, \dots, \varepsilon_n)^\top$  and

$$X = \begin{pmatrix} 1 & x_1 \\ \vdots & \vdots \\ 1 & x_n \end{pmatrix}$$

We assume that  $x_i$  are the values of the univariate covariate of interest and that  $\varepsilon \sim N(0, \sigma^2 I_n)$  where  $I_n$  denotes the  $n$ -dimensional unit matrix.

- (a) Derive the ordinary least squares (OLS) estimate for  $\beta$ .
- (b) Show that the OLS is unbiased and write down the variance of the estimate.
- (c) Show that the OLS estimate equals the maximum likelihood estimate.
- (d) Assume now that the residuals  $\varepsilon$  are correlated:  $\varepsilon \sim N(0, \Sigma)$  for some invertible covariance matrix  $\Sigma \in \mathbb{R}^{n \times n}$ . Derive the resulting maximum likelihood estimate and calculate its variance by deriving the Fisher information matrix.
- (e) Consider the OLS estimate from a). Give the conditions under which this estimate is still consistent. Justify your statements.

### Exercise 3

In a study on the undernutrition of children in developing countries, a random sample of 100 children under 5 years is drawn. It is recorded whether a child is undernourished or not, leading to the binary response variable

$$Y_i = \begin{cases} 1 & \text{child was undernourished,} \\ 0 & \text{otherwise.} \end{cases}$$

As explanatory variables the study recorded

$x_1$  family income per head per year (in \$), and

$x_2$  indicator:  $x_2 = 1$  for families that live in urban or city areas;  $x_2 = 0$  for families that live in a rural areas.

The parameter estimates of the resulting Logit model are

Variable	Estimate	p-Value
Intercept	3.3084	0.0000048
$x_1$	-0.0379	0.0000004
$x_2$	0.9298	0.2180000

- Write down the model equation of the Logit model.
- Interpret the effect of  $x_1$  ( $\hat{\beta}_1 = -0.0379$ ). Calculate the odds ratio for undernutrition comparing children living in the city/urban area compared to children living in a rural area.
- Interpret the p-values. Which effects are significant on a  $\alpha = 0.05$  significance level?
- Explain the problem of multiple testing and suggest a solution.

### Exercise 4

- Consider the following matrix

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 2 \\ 3 & 2 & 1 \end{pmatrix}.$$

Calculate the determinant of  $A$  manually, i.e. without software or a calculator.

- Assume that  $Y \sim N(0, \Sigma)$  whereby the covariance matrix  $\Sigma \in \mathbb{R}^{p \times p}$  is of full rank. Moreover, the eigenvalue decomposition of  $\Sigma$  is given by

$$\Sigma = U\Lambda U^\top,$$

where  $U \in \mathbb{R}^{p \times p}$  is the matrix of eigenvectors and  $\Lambda = \text{diag}(\lambda_1, \dots, \lambda_p)$  contains the eigenvalues of  $\Sigma$ . Standardize  $Y$ . I.e., construct a matrix  $A$  such that  $\tilde{Y} = AY$  is standard normal:

$$\tilde{Y} \sim N(0, I_p).$$

- Construct a univariate random variable  $X = a^\top Y$  with  $a^\top = (a_1, \dots, a_p)$  such that

$$\text{Var}(X) = \max_{\|\tilde{a}\|=1} \text{Var}(\tilde{a}^\top Y)$$

that is, the variance is maximal for all linear combinations of  $Y$ .

## Exercise 5

- (a) Assume that  $\lambda$  is gamma distributed, i.e.

$$\lambda \sim \frac{\lambda^{k-1} \exp(-\lambda/\theta)}{\theta^k \Gamma(k)},$$

where  $k > 0$ ,  $\theta > 0$  are the parameters of the gamma distribution. In short:  $\lambda \sim \Gamma(k, \theta)$ .  
For a given  $\lambda$  (i.e. conditional on  $\lambda$ )

$$Y|\lambda \sim \text{Poisson}(\lambda).$$

Derive the distribution of  $\lambda$  given  $Y$ .

- (b) In a Bayesian model, the prior distribution of the parameter  $\theta$  is denoted by  $g(\theta)$ .  
Given  $\theta$ ,  $Y$  is observed; i.e., we assume

$$Y|\theta \sim f(y|\theta).$$

Under which condition is the posterior mode (i.e. the maximum of the posterior distribution of  $\theta$  conditional on  $Y$ ) equal to the maximum likelihood estimate?
